

## Day 4 Evidence Workbooklet

### Comparisons and Boundary Cases

Engineering practice → threshold rule → Python comparison → boundary evidence → support route

Student copy. Guided workbooklet, not the mastery quiz. Print format: duplex, left-stapled packet.

| Name  |         | Section |               | Date |                                     |
|-------|---------|---------|---------------|------|-------------------------------------|
| Score | ____/40 |         | Mastery check |      | secure / developing / needs support |

Yesterday the pump-flow intake values were converted from text into numeric fields. Today the team uses those typed values to check a quality boundary: a flow reading is acceptable if it is inside a target band. The exact boundary rows matter because a reading exactly at the lower or upper limit may be allowed depending on the operator.

The problem today is comparison evidence: below, at, or above a limit; inclusive versus exclusive rules; and an exact sentence that explains a boundary case.

|                           |                                                                                                                         |
|---------------------------|-------------------------------------------------------------------------------------------------------------------------|
| <b>Engineering task</b>   | Check whether converted pump-flow readings meet an acceptable range before the team uses them in a go/no-go gate.       |
| <b>Computational move</b> | Evaluate one comparison at a time and explain exact-boundary cases without jumping ahead to compound decisions.         |
| <b>Python focus</b>       | <, <=, >, >=, ==, !=, comparison result, inclusive limit, exclusive limit.                                              |
| <b>Evidence to keep</b>   | reading value, boundary value, operator, true/false result, and a sentence explaining whether the boundary is included. |

### Day 4 boundary rules

1. A comparison expression produces **True** or **False**.
2. <= and >= include equality at the boundary.
3. < and > do not include equality at the boundary.
4. == checks equality; it does not assign a value.
5. A reliable threshold note names the value, the limit, the operator, and the result.

## 1 Read the threshold notebook one comparison at a time

[recognize](#)[predict](#)

Use the converted numeric fields from the intake record. Do not combine the comparisons yet; Day 5 will do that.

```
1 # Converted numeric fields from the intake record
2 target_flow_lpm = 20.0
3 low_limit_lpm = 19.6
4 high_limit_lpm = 20.4
5 reading_low_edge = 19.6
6 reading_middle = 20.0
7 reading_high_edge = 20.4
8 reading_high_miss = 20.5
9
10 # Individual comparison checks
11 reading_low_edge >= low_limit_lpm
12 reading_low_edge > low_limit_lpm
13 reading_high_edge <= high_limit_lpm
14 reading_high_edge < high_limit_lpm
15 reading_high_miss <= high_limit_lpm
16 reading_middle == target_flow_lpm
```

| Pts. | Prompt                                                          | My evidence |
|------|-----------------------------------------------------------------|-------------|
| 1    | Which variables define the lower and upper allowed flow limits? |             |
| 1    | Which reading is exactly equal to the lower limit?              |             |
| 1    | Which reading is exactly equal to the upper limit?              |             |
| 1    | Which reading is above the upper limit?                         |             |

## 2 Predict comparison results at exact boundaries

[predict](#) [explain](#)

Complete the table. Explain the result using the operator, not just the number.

| Pts. | Comparison expression                               | True or False? | Boundary reason |
|------|-----------------------------------------------------|----------------|-----------------|
| 2    | <code>reading_low_edge &gt;= low_limit_lpm</code>   |                |                 |
| 2    | <code>reading_low_edge &gt; low_limit_lpm</code>    |                |                 |
| 2    | <code>reading_high_edge &lt;= high_limit_lpm</code> |                |                 |
| 2    | <code>reading_high_edge &lt; high_limit_lpm</code>  |                |                 |

### Common trap to check

A reading exactly at the limit is included by `<=` or `>=`, but it is not included by `<` or `>`. The operator decides the boundary, not the word "limit" by itself.

### 3 Separate equality from assignment and mismatch checks

[recognize](#)[predict](#)

Python uses `==` for equality checks and `=` for assignment. This page keeps comparison evidence separate from stored state.

| Pts. | Expression or line                                  | Result or effect | What evidence does it create? |
|------|-----------------------------------------------------|------------------|-------------------------------|
| 2    | <code>reading_middle == target_flow_lpm</code>      |                  |                               |
| 2    | <code>reading_high_miss != target_flow_lpm</code>   |                  |                               |
| 2    | <code>reading_middle = target_flow_lpm</code>       |                  |                               |
| 2    | <code>reading_high_miss &lt;= high_limit_lpm</code> |                  |                               |

| Pts. | Prompt                                                                                     | My response |
|------|--------------------------------------------------------------------------------------------|-------------|
| 2    | Why is <code>==</code> a safer symbol than the word "is" when writing comparison evidence? |             |
| 2    | Why should a threshold note not say only "near the target"?                                |             |

#### 4 Build a boundary table before combining conditions

[trace](#) [explain](#)

Complete the boundary table. The last column should be a short engineering sentence, not only **True** or **False**.

| Pts. | Reading | Lower check: $\geq$<br>19.6 | Upper check: $\leq$<br>20.4 | Boundary evidence sentence |
|------|---------|-----------------------------|-----------------------------|----------------------------|
| 2    | 19.5    |                             |                             |                            |
| 2    | 19.6    |                             |                             |                            |
| 2    | 20.4    |                             |                             |                            |
| 2    | 20.5    |                             |                             |                            |

#### Bridge to Day 5

Tomorrow the team will combine separate comparison results into a go/no-go expression. Today the important habit is to make each comparison traceable first: value, operator, limit, result, and boundary sentence.

## 5 Debug a boundary claim

[debug](#) [test](#) [explain](#)

A teammate writes this note after checking the lower edge reading:

### Boundary note to debug

The 19.6 L/min reading fails because it is not greater than the lower limit of 19.6 L/min.

| Pts. | Prompt                                                                                               | My response |
|------|------------------------------------------------------------------------------------------------------|-------------|
| 2    | What part of the teammate's sentence uses a real comparison result?                                  |             |
| 2    | What rule did the teammate use that may not match the allowed boundary?                              |             |
| 2    | Write the inclusive comparison that would allow the exact lower-limit reading.                       |             |
| 2    | Rewrite the boundary note so it names the operator and explains whether the exact limit is included. |             |

### Boundary-test habit

When a threshold rule matters, test at least three rows: just below the boundary, exactly at the boundary, and just above the boundary. Exact-boundary rows catch many comparison mistakes.

## 6 Mastery check and support route

[transfer](#)[explain](#)

Use your own evidence from this workbooklet. Do not write a generic answer.

| Pts. | Prompt                                                                                                | My response |
|------|-------------------------------------------------------------------------------------------------------|-------------|
| 2    | Give one example where changing from $>$ to $>=$ changes the result at an exact boundary.             |             |
| 2    | In one or two sentences, explain why Day 3 type/cast evidence is needed before Day 4 boundary checks. |             |

### My mastery check

Mark the strongest statement that is true after this workbooklet.

|                          |                                                                                                               |
|--------------------------|---------------------------------------------------------------------------------------------------------------|
| <input type="checkbox"/> | Secure: I can evaluate comparison operators and explain exact lower or upper boundary cases.                  |
| <input type="checkbox"/> | Developing: I can evaluate some comparisons, but I still need support with inclusive versus exclusive limits. |
| <input type="checkbox"/> | Needs support: I need a smaller example before I can trust my boundary-check evidence.                        |

### My next support move

My issue is mostly: setup / Python syntax / tracing / operator choice / boundary cases / confidence / time.

The first boundary where I got uncertain was: \_\_\_\_\_

My next small action is: ask a partner / ask instructor / rebuild the boundary table / test just-below-at-above rows / try the recovery version.

*Workbooklet target: I can evaluate Python comparison operators, explain exact-boundary cases, and prepare separate comparison evidence before Boolean combinations.*
